Supplemental Report

RE: Texaco Adams "B" #1
Section 26-34-29
Meade County, Kansas.

Samples of the Mississippian-St. Louis have been examined and described:

Limestone - Tan, fine crystalline, chalky in part, oolitic with spotted poor porosity. No live oil stain but fair florescence.

This description covers the bottom 10' of the hole where the electric log indicates some broken porosity. Frequently the good porous zones in the St. Louis are not encountered in the first 90' (for example Kismet and Pretty Prairie). It is felt there is a good chance that the (B) and (C) zones could be developed down below.
